Abstract

At present it is believed that different multi-cluster structures for light nuclei may represent equivalent states of these nuclei. Here it is proven that once we take account of Three Body and Four Body Forces then this equivalence is lost.

For quite sometime now it has been becoming clear that the best microscopic calculations using successful Two Body Forces (2BF) for light nuclei $A=3,4$ give underbinding and too large a radii [1]. This pointed at the requirement of other forces like the Three Body Forces (3BF) and possible Four Body Forces (4BF). The improvements arising from the inclusion of 3BF are well known [2]. It has also been becoming clear that 4BF are essential for a good understanding of light nuclei [3].

Let us accept that 3BF and 4BF are needed in a basic way for the study of light nuclei [2,3]. It is important to note that these are genuine 3BF and 4BF which are irreducible to any 2BF etc. As nucleons have finite size and structure it is clear that there shall be genuine multi-body forces. These will manifest themselves in any physical situation where it would be essential to consider overlap of multi-nucleons [4-6]. However, how and why these multi-body forces arise is not the issue here. For our purpose here it is enough to accept the existence of 3BF and 4BF forces. This means that to get good description of $A=3,4$ nuclei we do need 3BF and 4BF in a basic way to fit to experimental quantities like binding energies, radii, charge distributions and excitation spectra of these nuclei.

Let the Hamiltonian for upto $A=4$ system be

$$H = \sum_i^A \frac{p_i^2}{2m} + \sum_{i<j}^A v_{ij} + \sum_{i<j<k}^A V_{ijk} + \sum_{i<j<k<l}^A V_{ijkl} \quad (1)$$

where v_{ij} , V_{ijk} and V_{ijkl} are NN, NNN and NNNN potentials respectively. For $A=2$ system only the first two terms would be present. While for $A=3$ system the NNN term would also be contributing. Only for $A=4$ system does the 4BF term contribute.

Now let us use this Hamiltonian to solve that $A=2,3,4$ body problems in nuclear physics. We may use the Quantum Monte Carlo method or some other method to obtain the best fits to all the relevant experimental quantities of these nuclei which are: 2H , 3H and 3He and 4He . Let us assume that we are able to do as good a job as possible. At the end of the day let the wave functions which provided these fits be $\psi_0(d)$, $\psi_0(t)$, $\psi_0(h)$ and $\psi_0(\alpha)$. (Note : $d={}^2H$, $t={}^3H$, $h={}^3He$ and $\alpha={}^4He$)

Note that all these wave functions are solutions of Hamiltonian which have components not present in all of these. For example the $A=4$ case the wave function has " wounds " inflicted by the 4BF which are not present

in the others. As such the wave function for A=4 case has components which can not be reduced to any (2-body)-(2-body) or (3-body)-(1-body) wave functions. In the same manner the A=3 case have "wounded" wave functions unique to themselves and irreducible to any other system of wave functions. These 3BF and 4BF "wounds" in the wave functions in a way are unique signatures of their presence in A=3 and 4 systems. Note that the A=2 case would have none of the "wounds" arising from 3BF or 4BF.

At present it is commonly believed that there exists equivalence of various multi-clusters for light nuclei. For example in the oscillator model the ground state of ${}^6\text{Li}$ is described by the following wave functions of equivalent forms [7,p.40, appendix C]

$$\psi_{gs}({}^6\text{Li}) = A\{\phi_0(\alpha)\phi_0(d)\chi(\alpha - d)\} = NA(\phi_0(t)\phi_0(h)\chi(t - h)) \quad (2)$$

Here $\chi(\alpha - d)$ and $\chi(t - h)$ are two oscillator quanta wave functions and $\phi_0(\alpha), \phi_0(d), \phi_0(t), \phi_0(h)$ are the internal wave functions. The constant N is here to ensure that the two functions are equal to each other. The mathematical equivalence of the two can be easily demonstrated. Since they are the same, these can exist simultaneously and also note that these are not orthogonal [7]. None of this is changed even with the hard core of the Jastrow form in the two body interaction [7, p.113]. This is the broad view which has been dominating the studies of light nuclei at present [7-9].

However, in the above mathematical proof, there is an underlying ansatz - which is that in the Schroedinger equation one need not go beyond 2BF and ignore all many body forces like the 3BF and 4BF [7, p.1]. However at present on the basis of what we have discussed above there is no way that one can do without 3BF and 4BF for these nuclei. Also due to the reasons indicated above the projection of the wave function

$$\phi_0(\alpha)\phi_0(d)$$

on

$$\phi_0(t)\phi_0(h)$$

would be zero. Hence the putative equivalence of different multi-clusters [7-9] for light nuclei and which forms the backbone of studies of nuclei at present is wrong and should be abandoned.
